

## BENZODIAZEPINES FOR TREATING OR PREVENTING RSV INFECTION

The present invention relates to a series of benzodiazepine derivatives which  
 5 are active against Respiratory Syncytial Virus (RSV).

RSV is a major cause of respiratory illness in patients of all ages. In adults, it  
 tends to cause mild cold symptoms. In school-aged children, it can cause a cold and  
 bronchial cough. In infants and toddlers it can cause bronchiolitis (inflammation of  
 the smaller airways of the lungs) or pneumonia. It has also been found to be a  
 10 frequent cause of middle ear infections (otitis media) in pre-school children. RSV  
 infection in the first year of life has been implicated in the development of asthma  
 during childhood.

Current anti-RSV therapy involves the use of a monoclonal antibody  
 to RSV, called palivizumab. Such use of palivizumab is a prophylactic, rather than  
 15 therapeutic, treatment of RSV. However, although this antibody is often effective, it  
 is expensive. Indeed, its expense means that it is unavailable for many people in  
 need of anti-RSV therapy. There is therefore an urgent need for effective  
 alternatives to existing anti-RSV therapy.

It has now surprisingly been found that the particular benzodiazepine  
 20 derivatives of the general formula (I) set out below are active against RSV.

Accordingly, the present invention provides, in a first embodiment, the use of  
 a compound which is (a) a benzodiazepine derivative of formula (I) or an N-oxide  
 thereof, or (b) a pharmaceutically acceptable salt thereof, in the manufacture of a  
 medicament for use in treating or preventing an RSV infection

Compounds of the formula (I) containing one or more chiral centre may be used in enantiomerically or diastereoisomerically pure form, or in the form of a mixture of isomers. For the avoidance of doubt, the chemical structures depicted

25 herein are intended to embrace all stereoisomers of the compounds shown, including racemic and non-racemic mixtures and pure enantiomers and/or diastereoisomers.

Preferred compounds of the invention are optically active isomers. Thus, for example, preferred compounds of formula (I) containing only one chiral centre

For the avoidance of doubt, the compounds of the formula (I) can, if desired, be used in the form of solvates.

Compounds of formula (I) may be prepared by reacting glyoxylic acid (HCO-CO<sub>2</sub>H), benzotriazole and an appropriate benzyl carbamate at reflux in toluene, under Dean-Stark conditions giving the key protected amino acid of formula (II)

The thus obtained amino acid of formula (II) can then be reacted with a suitable chlorinating agent, such as oxalyl chloride, followed by reaction with a 2-aminobenzophenone of formula (III)

to give the intermediate amide of formula (IV)

which need not be characterized.

- 5           The compound of formula (IV) can then be subjected to ammonolysis followed by ring closure in acetic acid containing ammonium acetate to obtain the protected benzodiazepine of formula (V)

- 10           The compound of formula (V) can then be deprotected using hydrogen bromide in acetic acid to yield the deprotected amine of formula (VI).

Compounds of formula (I), in which X is -CO- or -CO-NR' can be prepared by reacting a compound of formula (VI), as defined above, with an acid anhydride in a suitable solvent, preferably pyridine at ambient temperature, or with an acid chloride in a suitable solvent in the presence of a base, preferably in THF at ambient temperature with triethylamine present. Alternatively, the compounds can be produced by reaction of a compound of formula (VI) with an acid in a suitable solvent in the presence of a base and a coupling agent, preferably in THF at ambient temperature with triethylamine and *O*-benzotriazol-1-yl-N, N, N', N'-tetramethyluronium hexafluorophosphate (HBTU) present.

If the acid chloride used is an amino carbonyl chloride, the compound of formula (I) is a urea. In the case where R' in the X moiety is hydrogen, such compounds may also be prepared by the reaction of a compound of formula (VI) with an isocyanate. This reaction is preferably carried out in THF at ambient temperature. Alternatively, the isocyanate may be prepared *in situ* from the relevant amine and phosgene, in the presence of a base, usually triethylamine, again in THF. Compounds in which R' is other than hydrogen can, of course, be prepared by reacting a corresponding compound in which R' is hydrogen with an appropriate alkylating agent, for example L-(C<sub>1</sub>-C<sub>6</sub> alkyl) wherein L is a leaving group, for example chlorine.

Compounds of formula (I), in which X is -S(O)<sub>2</sub>- may be prepared by the reaction of a compound of formula (VI) with a suitable sulfonyl chloride. Similarly, compounds of formula (I), in which X is -S(O)- may be prepared by the reaction of a compound of formula (VI) with a suitable sulfinyl chloride

In the preparation of the benzodiazepine skeleton, commercially available aminobenzophenone compounds of formula (III) can be used where possible. Compounds of formula (III) which are not commercially available can be prepared by known methods, for example by reaction of a Weinreb type amide of formula (VII)

with a group  $R^1$ -Li or a Grignard reagent such as  $R^1$ -MgBr. Preferably this reaction is carried out in THF at  $-100^\circ\text{C}$ .

Compounds of formula (VII) are known compounds or can be prepared by analogy with known methods. For example, they can be prepared from the reaction of isatoic anhydrides of formula (VIII)

with N,O-dimethyl hydroxylamine under standard reaction conditions.

The starting materials of formula (II), (III), (VII), and (VIII) are known compounds, or may be prepared by analogy with known methods.

Further synthetic manipulation of the thus obtained compounds of formula (I) may be carried out by conventional methods to achieve further compounds of formula (I). The benzodiazepines of formula (I) can be salified by treatment with an appropriate acid or base.

Although the described route to the claimed compounds provides an adequate synthesis for laboratory scale preparations, an alternative route was sought which has potential as a manufacturing route. The same starting material (2-amino-benzophenone) (1) is used in both, however in the alternative route, the benzodiazepine ring system is formed by reaction initially with bromoacetyl bromide (or an equivalent reagent) followed by ring closure with ammonia. These reactions are carried out in a suitable solvent, such as dichloromethane, and at a suitable temperature which may range from  $-20$  to  $150^\circ\text{C}$ . In order to protect the NH functionality, at this stage the unsubstituted benzodiazepine is reacted with a base, and an alkylating agent. For instance sodium hydride in DMF followed by addition of 4-methoxy-benzyl chloride gives rise to the intermediate (2) shown below.

Further reaction of this material with a base (e.g. potassium tert-butoxide ) in a suitable solvent (e.g. THF or DMF) followed by quenching with isoamyl nitrite (or an alternative similar reagent) furnishes the oxime intermediate (3) which may be converted into the racemic primary amine by methods which include the use of

5 hydrogen and a suitable catalyst. This amine then undergoes a Dynamic Kinetic Resolution (DKR) procedure by which the racemic amine in the presence of a suitable optically active acid, and a suitable aldehyde gives rise to precipitation of the salt of the desired (S)-amine (4) in good yield and exceptionally high enantiomeric excess. A suitable acid for this conversion can be e.g. Camphorsulfonic acid, Boc-

10 phenyl alanine or the like, and a suitable aldehyde may be a benzaldehyde such as 3,5-dichloro salicylaldehyde.

The optically amine thus formed may then be transformed into a desired derivative, such as an amide or urea. The amide formations may be carried out using a suitable carboxylic acid and a coupling reagent, or a carbonyl chloride or other

15 suitable reagent, and the ureas prepared using either a suitable isocyanate, or alternatively reaction with phosgene followed by a suitable amine.

These derivatives thus formed may then have the protecting group removed. This may be carried out in the presence of a Lewis Acid, such as aluminium chloride, boron trifluoride, titanium tetrachloride, or the like. These reactions are carried out

20 in a suitable inert solvent, such as dichloromethane. Reaction temperatures may range from -20 to 150°C, but are typically carried out at room temperature or below.

As explained above, the compounds of the invention are active against RSV. The present invention therefore provides a method for treating a patient suffering from or susceptible to an RSV infection, which method comprises administering to said patient an effective amount of a compound of formula (I) or a pharmaceutically acceptable salt thereof.

RSV is prevalent among children younger than two years of age, adults suffering from asthma, chronic obstructive pulmonary disorder (COPD) or immunodeficiency and the elderly. It is a particularly serious risk amongst children who suffer from chronic lung disease. Accordingly, the said composition or medicament is typically for use in treating a patient who is a child under two years of age, patients with asthma, COPD or immunodeficiency the elderly or persons in long term care facilities. Typically, said child suffers from chronic lung disease.

Further, anti-RSV prophylaxis is recommended for infants born at 32 weeks of gestation or earlier, until they reach 6 months of age, the elderly, persons with immunodeficiency and those in long term care facilities. Accordingly, the said composition or medicament is typically for use in preventing RSV infection in an infant less than 6 years of age, who was born after 32 weeks of gestation or less, the elderly, persons with immunosufficiency and those in long term care facilities.

It has been shown that RSV infections are accompanied by inflammatory reactions (Noah et al, Clinical Immunology 2000, Vol 97, 43-49). The present invention also relates to a combination of a compound of formula (I), or a pharmaceutically acceptable salt thereof, with an anti-inflammatory compound and the use of such a combination in the treatment of RSV. Typically, said anti-inflammatory compound is a steroid, for example budesonide or fluticasone, a non-steroid, for example a leukotriene antagonist, phosphodiesterase 4 inhibitor or TNF alpha inhibitor or an interleukin 8 or interleukin 9 inhibitor.

Thus, in one embodiment, a compound of formula (I), or pharmaceutically acceptable salt thereof, is combined with a steroid antiinflammatory compound, for example budesonide or fluticasone. In a preferred embodiment, the steroid is administered in low doses to minimize immuno-suppressant effects. In another embodiment a compound of formula (I), or a pharmaceutically acceptable salt thereof, is combined with a non-steroid anti-inflammatory compound, for example leukotriene antagonists such as Singulair (Merck) or Accolate (Astra Zeneca), phosphodiesterase 4 inhibitors such as roflumilast (Altana), TNF alpha inhibitors such as Enbrel (Amgen), Remicade (Centocor), Humira (Abbott) or CDP870 (Celltech) or NSAIDS. In a further embodiment, a compound of formula (I) is combined with interleukin 8 or interleukin 9 inhibitors. The present invention thus also relates to a product containing a compound of formula (I), or a pharmaceutically acceptable salt thereof, and an anti-inflammatory compound for simultaneous, separate or sequential use in the treatment of RSV.

The present invention also relates to a combination of a compound of formula (I), or a pharmaceutically acceptable salt thereof, with an anti-influenza compound and the use of such a combination in the treatment of concomitant RSV and influenza infections. The present invention thus also relates to a product containing a compound of formula (I), or a pharmaceutically acceptable salt thereof, and an anti-influenza compound for simultaneous, separate or sequential use in the treatment of concomitant RSV and influenza infections.

It is a further surprising finding of the present invention that compounds of the invention are active against human metapneumovirus, measles, parainfluenza viruses, paramyxoviruses and mumps. The present invention thus provides the use of a compound of formula (I), or a pharmaceutically acceptable salt thereof, in the

manufacture of a medicament for use in the treatment of human metapneumovirus, measles, parainfluenza viruses, paramyxoviruses and mumps.

The compounds of the invention may be administered in a variety of dosage forms. Thus, they can be administered orally, for example as tablets, troches, 5 lozenges, aqueous or oily suspensions, dispersible powders or granules. The compounds of the invention may also be administered parenterally, whether subcutaneously, intravenously, intramuscularly, intrasternally, transdermally or by infusion techniques. The compounds may also be administered as suppositories.

In a preferred embodiment, the compounds of the invention are administered 10 by intranasal or intrabronchial administration. The present invention also provides an inhaler or nebuliser containing a medicament which comprises (a) a benzodiazepine derivative of the formula (I), as defined above, or a pharmaceutically acceptable salt thereof, and (b) a pharmaceutically acceptable carrier or diluent.

The present invention also provides a pharmaceutical composition 15 containing such a benzodiazepine derivative, or a pharmaceutically acceptable salt thereof, and a pharmaceutically acceptable carrier or diluent.

Said pharmaceutical composition typically contains up to 85 wt% of a compound of the invention. More typically, it contains up to 50 wt% of a compound of the invention. Preferred pharmaceutical compositions are sterile and pyrogen free. 20 Further, the pharmaceutical compositions provided by the invention typically contain a compound of the invention which is a substantially pure optical isomer.

The compounds of the invention are typically formulated for administration with a pharmaceutically acceptable carrier or diluent. For example, solid oral forms may contain, together with the active compound, diluents, e.g. lactose, dextrose, 25 saccharose, cellulose, corn starch or potato starch; lubricants, e.g. silica, talc, stearic acid, magnesium or calcium stearate, and/or polyethylene glycols; binding agents; e.g. starches, arabic gums, gelatin, methylcellulose, carboxymethylcellulose or polyvinyl pyrrolidone; disaggregating agents, e.g. starch, alginic acid, alginates or sodium starch glycolate; effervescing mixtures; dyestuffs; sweeteners; wetting 30 agents, such as lecithin, polysorbates, laurylsulphates; and, in general, non toxic and pharmacologically inactive substances used in pharmaceutical formulations. Such pharmaceutical preparations may be manufactured in known manner, for example, by means of mixing, granulating, tableting, sugar coating, or film coating processes.

Liquid dispersions for oral administration may be syrups, emulsions and suspensions. The syrups may contain as carriers, for example, saccharose or saccharose with glycerine and/or mannitol and/or sorbitol.

Suspensions and emulsions may contain as carrier, for example a natural gum, agar, sodium alginate, pectin, methylcellulose, carboxymethylcellulose, or polyvinyl alcohol. The suspension or solutions for intramuscular injections may contain, together with the active compound, a pharmaceutically acceptable carrier, e.g. sterile water, olive oil, ethyl oleate, glycols, e.g. propylene glycol, and if desired, a suitable amount of lidocaine hydrochloride.

Solutions for injection or infusion may contain as carrier, for example, sterile water or preferably they may be in the form of sterile, aqueous, isotonic saline solutions.

A therapeutically effective amount of a compound of the invention is administered to a patient. A typical dose is from about 0.001 to 50 mg per kg of body weight, according to the activity of the specific compound, the age, weight and conditions of the subject to be treated, the type and severity of the disease and the frequency and route of administration. Preferably, daily dosage levels are from 5 mg to 2 g.

Certain benzodiazepine derivatives of the formula (I) are novel *per se*. The present invention includes these novel compounds and pharmaceutically acceptable salts thereof. The present invention therefore also provides compounds of formula (Ib), or a pharmaceutically acceptable salt thereof

wherein  $R_1$ ,  $R_3$ ,  $n$ ,  $R_4$ ,  $X$  and  $R_5$  are as defined above.

Typically, in the formula (Ib),  $R_1$  is an unsubstituted phenyl group.

Typically, in the formula (Ib), when  $A_1$  is a heteroaryl group, it is other than a 5-methyl-isoxazolyl moiety.

Typically, in the formula (Ib),  $A_1$  is an aryl or heteroaryl moiety.

Typically, in the formula (Ib), X is -CO- or -CO-NR', wherein R' is as defined above, provided that when X is -CO-NR', the moiety -A<sub>1</sub>-Y-A<sub>2</sub> is -phenyl-O-phenyl.

Typically, in the formula (Ib), A<sub>2</sub> is other than a 4- to 10- membered saturated cycloalkyl ring, in which one of the carbon atoms is replaced by a N atom. In particular, A<sub>2</sub> is typically other than a substituted or unsubstituted moiety of the formula

wherein n and m are the same or different and each represent an integer of from 1 to 4.

Typically, in the formula (Ib), A<sub>2</sub> is a piperazinyl, pyridyl, pyrrolidinyl, pyrazinyl, cyclopropyl, phenyl or S,S-dioxo-thiomorpholino group which is unsubstituted or is substituted by a C<sub>1</sub>-C<sub>2</sub> alkyl group.

The present invention also relates to the novel compounds, as defined above, or a pharmaceutically acceptable salt thereof, for use in a method of treating the human or animal body. The present invention also relates to a pharmaceutical composition comprising a novel compound as defined above and a pharmaceutically acceptable diluant or carrier. Preferably, the pharmaceutical composition comprises a pharmaceutically acceptable salt of a novel compound as defined above. A pharmaceutically acceptable salt is as defined above. The novel compounds of the invention are typically administered in the manner defined above and the compounds are typically formulated for administration in the manner defined above.

Preferably, the pharmaceutical compositions comprise optically active isomers of the novel compounds of the invention. Thus, for example, preferred novel compounds of the invention containing only one chiral centre include an R enantiomer in substantially pure form, an S enantiomer in substantially pure form and enantiomeric mixtures which contain an excess of the R enantiomer or an excess of the S enantiomer. It is particularly preferred that pharmaceutical contains a compound of the invention which is a substantially pure optical isomer. For the

avoidance of doubt, the novel compounds of the invention can, if desired, be used in the form of solvates.

The following Examples illustrate the invention. They do not however, limit the invention in any way. In this regard, it is important to understand that the  
5 particular assays used in the Examples section are designed only to provide an indication of anti-RSV activity. There are many assays available to determine the activity of given compounds against RSV, and a negative result in any one particular assay is therefore not determinative.

### ACTIVITY EXAMPLE 1

Mouse monoclonal antibodies to the phosphoprotein (P), nucleocapsid (N) & fusion (F) proteins of RSV and a rabbit anti-mouse- horseradish peroxidase (HRP) conjugated secondary antibody were used to demonstrate a reduction in RSV antigen via conversion of the o-phenylene diamine dihydrochloride (OPD) substrate to a coloured product. This was quantified by optical density (OD) measurement.

This assay was set up using all 96 wells of flat-bottomed 96-well plates. The outer wells were not subjected to any greater amount of evaporation than the inner wells during the 3 day assay period. (ie. No “edge effect” seen).

Plates were set up one day before addition of virus and compounds. The assay then ran for 3 days with ELISA development taking place on the 4<sup>th</sup> day.

#### **Day 0**

##### Set up of Assay Plates

All 96 wells of a microtitre plate were seeded at a density of  $4 \times 10^3$  Hep-2 cells/well in 100  $\mu$ l/well of Growth Medium (GM) consisting of Dulbecco's MEM (DMEM) with Glutamax-1, Sodium Pyruvate, 1000 mg/l glucose and pyridoxine (Invitrogen, catalogue number 21885-025) and supplemented with 10%FBS. (See Plate 1).

In tissue culture, the cells adhere to the tissue culture flask and were grown at 37°C, 5% CO<sub>2</sub> until 90% confluent.

Monolayers were washed with 20ml sterile PBS to remove serum and treated with 1ml trypsin to detach cells from the flask.

Cells were suspended in a small known volume of growth media and counted using a haemocytometer. The cell suspension was made up to the desired concentration in growth medium and added to wells by multichannel pipette. Brief, gentle shaking encouraged the cells to disperse more evenly across the well.

- Plates were kept undisturbed at 37°C in a 5% CO<sub>2</sub> atmosphere for 24hrs during  
 5 which time the cells settle to form an even cell monolayer.

**Day 1**Addition of Virus

- 10 A frozen vial of RSV (RSS strain provided by Virogen Ltd) stock solution was removed from the -80 freezer or liquid nitrogen store and diluted to a known Multiplicity of Infection (m.o.i) in Growth Medium.

- The m.o.i. was calculated by prior titration of the virus stock (by the ELISA assay method) as the virus input required to achieve a window of at least 0.8 OD  
 15 units between infected and uninfected control wells.

$$\text{Multiplicity of Infection} = \frac{\text{plaque forming units per well (pfu/well)}}{\text{number of cells per well}}$$

- 20 50µl of diluted virus was added to infected, “virus+”, wells by multichannel pipette; 50µl of Growth Medium was added to uninfected, cell control wells (CC) by multichannel pipette. (See Plate 2)

Sides of plates were marked with stripes to identify plates in the event of lids becoming separated.

Plates were incubated at 37°C for 1hr to allow virus adsorption.

#### Compound Dilutions

Compounds were made up at 4x strength in GM containing 2% DMSO (a final DMSO concentration in the assay of 0.5%).

Six compounds were tested on each assay plate as illustrated below. (See Plate 3). Compounds were tested in duplicate wells across a 7-point dilution series (from 50µM-0.78µM): in the presence of virus.

Virus infected, untreated wells served as the virus control (VC); Uninfected, untreated wells serve as the cell control (CC). The difference in absorbance between CC and VC wells constitutes the assay window.

#### Dilution Plate Set Up

Compounds were serially diluted out in a separate microtitre plate as follows.

20 (See Plate 4)

200µl of GM containing 2% DMSO was added to all wells except the '50µM' or first column, to which 392µl of GM was added. 8µl of each test compound was cherry-picked from a thawed Arrow screening plate and transferred to the appropriate well in the '50µM' column. Since the compound stock was at 10mM in 100% DMSO, this will maintain the DMSO level at 2% at the top compound concentration.

25

Using a multichannel pipette, 200µl was transferred from the 50µM column to the 25µM column, then to the 12.5µM column and so on across the dilution plate creating a serial doubling dilution. Compounds were mixed upon transfer and tips changed between transfers, ensuring also that no compound was transferred to the

5 last column of compound-free wells (0µM).

#### Addition of Compound

The dilution plate was turned lengthways and 50µl of compound easily transferred by multichannel pipette from the dilution plate to the assay plate, column by column. There was therefore an excess of 100µl remaining in the dilution plate.

15 Plates were incubated at 37°C, 5% CO<sub>2</sub> for 3 days.

#### ELISA Stage

##### **Day 4**

20

Media was tapped out from wells directly into Virkon (1% solution in water) and plates were washed by immersing in a plastic box containing PBS. 50µl/well of 75%/25% vol/vol acetone/methanol fixative was added by multichannel pipette and left for 3mins.

25 Acetone/methanol was discarded from wells into Virkon and wells were washed with PBS as above.

Some 200µl of blocking solution (2% Marvel in PBS containing 0.05% Tween) was added per well by multichannel pipette. Plates were incubated at 37°C in a shaking incubator for 60mins.

Block solution was discarded down the sink and diluted primary antibody  
5 was added directly to wells (ie. no washing required).

RSV mouse monoclonal antibody NCL-RSV3 (Novocastra ) was diluted 1/400 in PBS/2% Marvel/0.05% Tween and 50µl was added per well. Plates were incubated at 37°C in a shaking incubator for 90mins.

Antibody was discarded down the sink and plates were washed 4 times by  
10 immersion in PBS/0.05% Tween.

DAKo rabbit anti-mouse HRP conjugate (DAKO catalogue number P0260) was diluted 1/1000 in PBS/2% Marvel/0.05% Tween and 50µl was added per well. Plates were incubated at 37°C in a shaking incubator for 60mins.

Antibody was discarded down the sink and plates were washed 6 times by  
15 immersion in PBS/0.05% Tween.

Substrate (SigmaFast OPD) was prepared in advance by dissolving 1 urea tablet in 20mL water. 1 OPD tablet was added to the urea solution just prior to use (NB. OPD was light sensitive) and vortexed to mix. 50µl of substrate was added per well.

20 The reaction was stopped by addition of 25µl/well of 20% sulphuric acid, once sufficient colour had developed but while cell control background was still low (~5 minutes).

Plates were read on a SpectraMax (Molecular Devices) spectrophotometer at wavelength 490nm and utilize the SOFTmax Pro software package.

25 The wells were emptied, washed in tap water and the monolayers stained with 50µl/well of 2% crystal violet in 20% methanol/water for at least 1 hour. The wells were then washed and air-dried and the monolayers examined under the microscope for indications of cell toxicity.

### 30 Results

SOFTmax data files were exported to Excel. Data handling used Excel templates written in-house for plotting dose response curves graphically and calculating IC50 values from the curves obtained.

All replicate wells were meaned. The assay window was calculated by subtracting the meaned cell control (CC) from the meaned virus control (VC). For each compound, the meaned CC was subtracted from the meaned values for each concentration point. The % of control was then calculated for each concentration point as a percentage of the window.

% of control was plotted against compound concentration. A straight line was fitted to the curve and the slope and intercept functions were used to calculate the IC<sub>50</sub>.
